

Tool-Use Decision Mechanism

Instruction cues are integrated, converted into an output-route decision, then distributed toward tool construction and direct-answer suppression.

Circuit-Level View

A continuous route score is formed on MLP11 -> MLP16 -> MLP19. It is not a fixed cross-layer vector; it is progressively re-encoded and then distributed downstream.

Current mechanistic picture: a shared decision spine first forms an output-route preference, then forks toward direct-answer suppression and fans out toward tool-side construction.
